1 NETWORK ARCHITECTURE

Our colorization model consists of five parts, the backbone network, color modeler, color generator, *RefineNet* and *SPixNet*. We detail their architecture parameters in Table 1.

2 ADDITIONAL COMPARATIVE RESULTS

Comparison with random hints. Thanks to the property of global coverage, our located anchors can represent the color distribution of the whole image. To study the necessity, we compare our method with a naive baseline that allocates the anchors randomly. Fig. 1 shows two examples, which obviously tells the limitation of this baseline, i.e. many parts of the image still suffer from color ambiguity and thus cause desaturated colors.

Structural coherence achieved by our color modeler. As described in the main paper, the color modeler that predicts color probability for each superpixel primitive holds a decent structural coherence, which is attributed to the shared backbone feature with the anchor-guided color generator. To verify this speculation, we construct a baseline by removing the anchor-guided color generation branch. For both methods, we sample the color of the highest probability for each primitives. Fig. 2 illustrates two examples, indicating that the color modeler of our model (b) achieves more consistent color distribution than the baseline (a).

More comparison with prior arts. In the main paper, we only qualitatively compare with the most competitive methods (i.e. UGColor [Zhang et al. 2017], Deoldify [Antic 2019], ColTran [Kumar et al. 2021]) to avoid distraction. Here we provide the full visual

Fig. 2. Colorization through independently color sampling.

comparison with all the existing competitors as introduced in the paper. Firstly, we provide the results of CIColor [Zhang et al. 2016], UGColor [Zhang et al. 2017], and ChromaGAN [Vitoria et al. 2020] on the challenging examples and real-world legacy photos in Fig. 3 and Fig. 4 respectively. Additionally, we illustrate more qualitative comparison in Fig. 5 and Fig. 6. All the results of our method are generated by our default model, without any hyper-parameters tuning.

Table 1. Parameter illustration of network architectures. C(k,s,n) denotes a Convolutional layer with kernel size k, stride size s, and output channels of n. Accordingly, deC(k,s,n) denotes a transposed-convolutional layer. ResBlock(n) denotes a ResBlock with channel number of n. T(d1,d2,h) denotes a Transformer encoder layer with basic channel number of d1, forward channel number of d2, and self-attention head number of h. $\uparrow_{\times 2}$ denotes upsampling feature maps by twice (nearest neighbor). '+' denotes channel-wise addition while \oplus denotes channel-wise concatenation.

Recently, GPColor [Wu et al. 2021] is proposed to utilize GAN inversion to generate a semantically related reference image for example-based colorization. Although it is an example-based colorization inherently, it could be used as a fully automatic colorization method in practice. In Fig. 7, we provide the qualitative comparison on several examples (of ImageNet) provided by the authors. Thanks to the automatically generated color reference image, GPColor can generate colorful results in most cases. However, it inherits the poor generalization from the image synthesis GAN, namely the GAN

trained on ImageNet can not properly synthesize image contents beyond this dataset. Remarkably, our method even holds superiority to this example-based colorization in most cases.

3 SAMPLES USED IN USER STUDY

In user study, we randomly select 30 samples from the validation set of COCO-Stuff, 3 of which are fully grayscale and thus get excluded in the study. So, there are 27 samples are used in this user study. The ground-truth samples are illustrated in Fig. 8 for reference. It

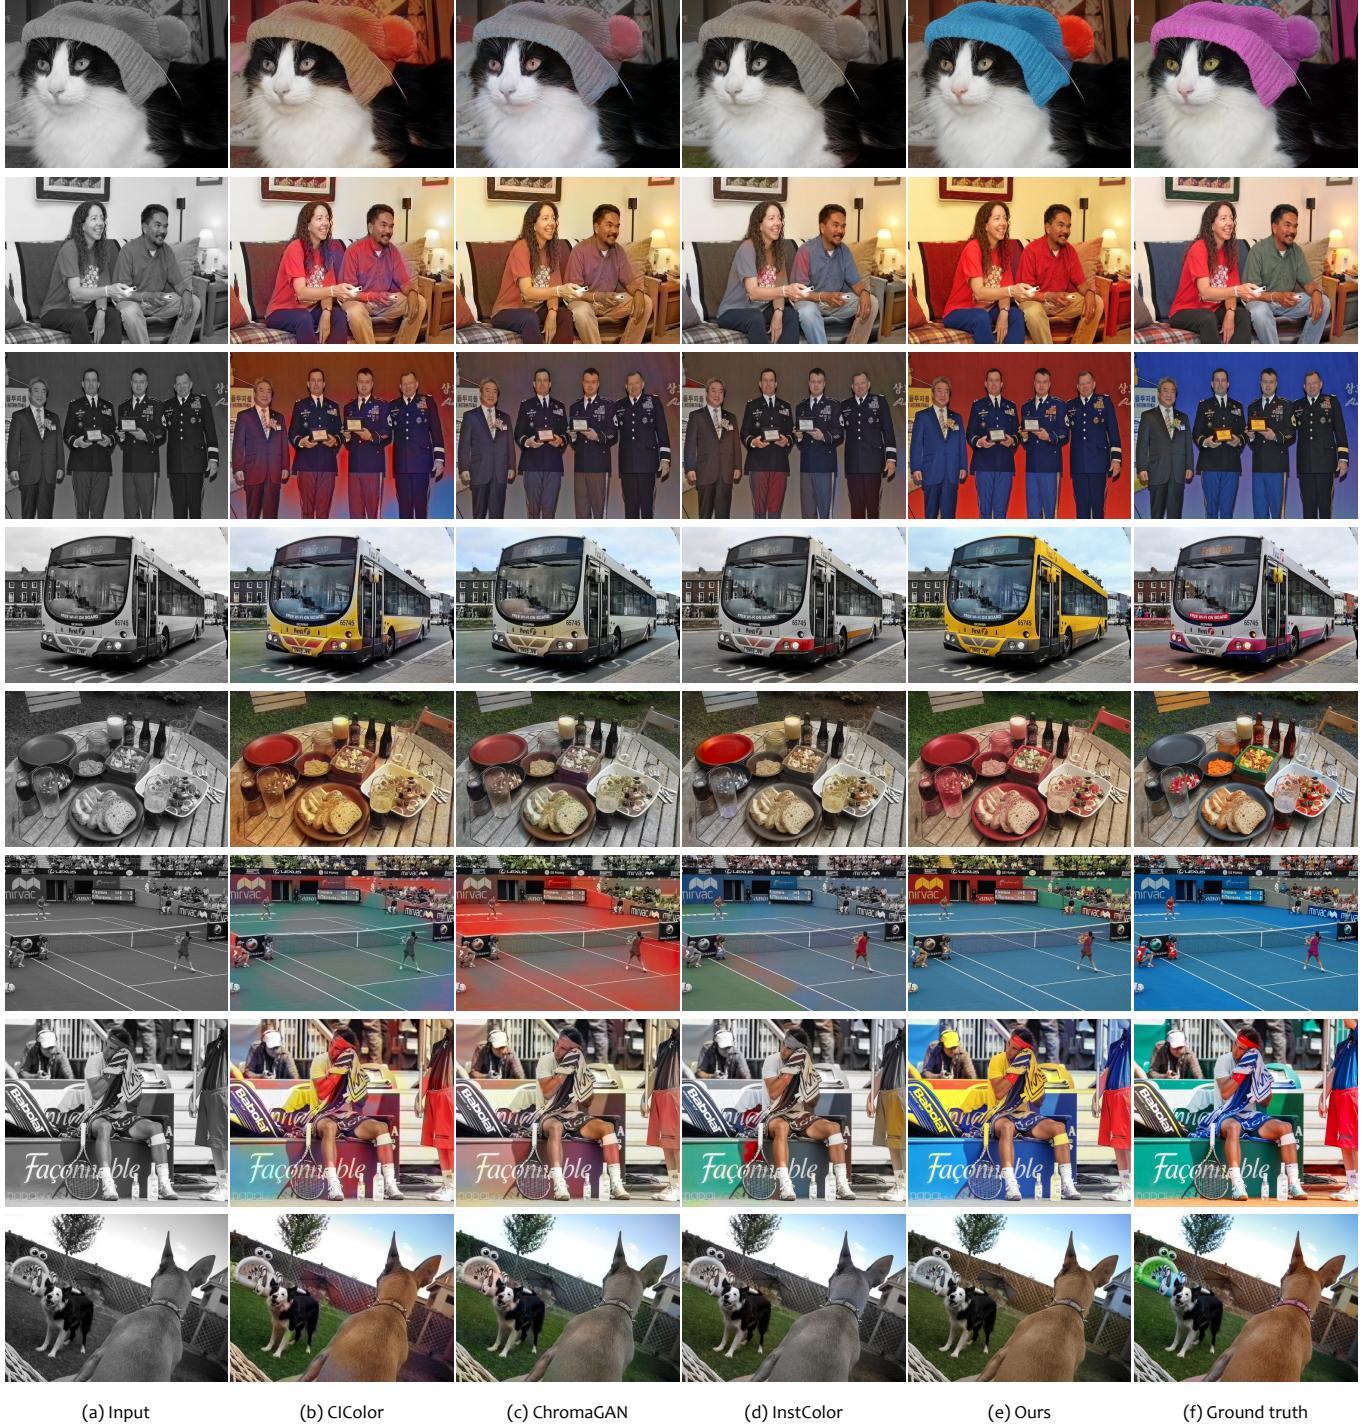

Fig. 3. Visual comparison on challenging cases. Here our competitors include CiColor, ChromaGAN, and InstColor.

includes images of diverse categories, such as the relatively easy natural scenes and challenging man-made objects.
